MATH240 Introduction to Probability and Statistics for Engineers
Project 2: Identifying Continuous Random Variables
Number of Young People Neither in Employment nor in Education or Training

In this project, what has been focused is the number of young people aged between 15-24 that are neither in employment nor in education or training in the year 2020. Numbers that we have for this statistic is total number of young people aged between 15-24, young people that neither in employment nor in education or training, and the rate of their number.

To make following the data easier, the numbers can be collected into one simple table:

Number of young people aged 15 - 24 neither in employment nor in education or training, 2020		
Population between aged 15-24		
Year	Total	Neither in employment nor in education or training	Neither in employment nor in education or training rate (NEET) (%)
Toplam-Total			
2020	**11 711**	**3 317**	**28,3**
Erkek-Male			
2020	**5 971**	1 266	21,2
Kadın-Female			
2020	**5 740**	2 051	35,7
Source: TurkStat, Labour Force Statistics, 2020 Figures in table may not add up to totals due to rounding.			

About this topic's calculations, let us assume that 1000 people will be selected randomly out of 11711 which is the total number of population between aged 15-24. That makes our probability of being neither in employment nor in education or training 0.283 (if the number is 3317 out of 11711, then out of 1000 will be 283). So, since our p = 0.283 and q = (1 − p) = 0.717, we can now find the mean and the standard deviation:

$$\mu = np = 1000 * (0.283) = 283$$

and

$$\sigma = \sqrt{(npq)} = \sqrt{1000 * 0.283 * 0.717} \cong 14.245$$

Now let us assume that it is asked to find the probability between 275 and 300 people are neither employed nor in education or training out of 1000 that was selected randomly:

$$P(a < X < b) = P(275 < X < 300) = P(X < 300) - P(X < 275)$$

Calculation of this probability can easily be done with the usage of Normal Distribution to Binomial Distribution:

$$Z = \frac{X - \mu}{\sigma}$$

$$Z_1 = \frac{300 - 283}{14.245} \cong 1.19 \quad \text{and} \quad Z_2 = \frac{275 - 283}{14.245} \cong -0.56$$

Since we know our Z values, we can calculate the are between them by finding their equivalents from z table:

$$P(X < 300) - P(X < 275) = P(Z < 1.19) - P(Z < -0.56) = 0.8830 - 0.2877 = 0.5953$$

       In conclusion, we can find probabilities that is asked about the table above with using relevant parameters (n, p, q, μ, σ) and normal distribution. Therefore, as a result of our calculations, now we can see that with the given numbers and parameters the probability of between 275 and 300 young people to be neither in employment nor in education or training out of 1000 is possible, which is very close to 60%. And lastly, the factors that may affect our calculations are the differences in parameter values which might be the change on the numbers of people in the table (will affect n, p, and q directly; μ and σ indirectly) or might be the change in the given X values (will affect Z values and the final answer).
